Open-Minded

INTRODUCTION

Ulcerative colitis (UC), characterized by periods of active disease and remission, is challenging to manage. Recent studies have identified mucosal healing as an optimal patient outcome.

AIMS

In this study, we investigated whether blood and fecal biomarkers of inflammation are able

To distinguish between mucosal healing defined by endoscopy from intestinal inflammation,

To differentiate between clinical remission and sustained clinical remission and

To show predictive value for a flare if levels at baseline are elevated.

METHODS

Endoscopy (Index EI - Rachmilewitz <=1 indicating mucosal healing) (baseline, 12 month), clinical activity index (CAI - Rachmilewitz), fecal Lactoferrin (FLA; cut-off: >=7.25µg/g), Calprotectin (CAL;>50µg/g) and PMN-Elastase (PMN-e;>0.062µg/g) (IBD-SCAN from Techlab, Blacksburg, USA for lactoferrin, ELISA-Kits from Immundiagnostik, Bensheim, Germany for calprotectin and PMN-elastase), serum CRP (≥0.5mg/dl) and white blood count (WBC>8.5/nl) (baseline, 1, 3, 6, 9, 12 month) were determined repeatedly and in events of acute flares.

Clinical status was **defined by the CAI** as follows: Patients in an acute clinical flare (CAI > 4), in clinical remission (CAI≥2 and ≤4) and in sustained clinical remission (CAI < 2, normal bowel frequency and no blood in stool).

Inflammatory status was **defined by the CAI and endoscopy** as follows: Patients in an acute clinical flare and endoscopic intestinal inflammation, patients in clinical remission and endoscopic intestinal inflammation, Patients in clinical remission and mucosal healing.

RESULTS

Table 1: Median, range and p-values of the five diagnostic biomarkers as **defined by the CAI.**

Diagnostic tool median ± STD	Acute clinical flare CAI>4 N = 52	clinical remission CAI≤2 and ≤4 N = 119	sustained clinical remission CAI<2 N = 358	p-value from Mann Whitney U
Lactoferrin	33.1 (0.1 – 145.0)	20.0 (0.1 – 167.6)		0.109

SUMMARY OF RESULTS

In 91 patients (45 female, mean age 52±13.4 years), 620 CAI and 179 endoscopies were performed.

A total of 42 (46%) patients developed a clinical flare.

Results for **Clinical status** as **defined by the CAI** are shown in table 1 and 3.

Results for **Inflammatory status** as **defined by the CAI and endoscopy** are shown in table 2 and table 4.

Using pre-defined cut-offs, only increased levels for FLA at baseline were associated with a significant higher risk of flaring (RR 1.69, p=0.018).

Using optimized cut-offs (for FLA were 11.9µg/g, CAL 13.9µg/g, PME-e 0.035µg/g and CRP 0.25mg/dl), patients with elevated FLA at baseline had a relative risk (RR) of 1.99 (95% CI 1.47-2.71, p<0.000) to develop a flare, CAL RR=1.58, (1.20–2.09, p<0.000) PMN-e RR=1.67 (1.21–2.29, p<0.000), CRP: RR=1.52 (1.15–2.0, p<0.001) (WBC: n.s.) as shown in table 5.

CONCLUSIONS

Fecal biomarkers have the potential to distinguish between mucosal healing and intestinal inflammation and to differentiate between active clinical flare and sustained clinical remission. Using pre-defined cut-offs, only fecal lactoferrin had predictive potential. Using optimized cut-offs, FLA, Cal, PMN-e and CRP were predictive of a flare.
